California Institute of Technology

# Tutorial Introduction

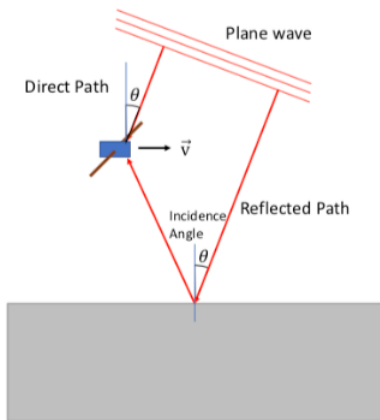

## Abstract

Passively sounding icy and rocky bodies in our Solar System provides a way to observe the surface and subsurface of these objects without the need for costly transmitters. Jupiter's decametric radiation provides a suitable source of RF for sounding on geological scales of interest, but its spectral structure is non-ideal for sounding. We present conditioning processes that improve the echo detectability and sounding resolution for Jovian burst-like signals. More than 18 hours of Jovian burst recordings are used to simulate the consequences of the natural spectral variation, and the attainable improvement with these processes for noise conditions in the Jovian and Earth/Moon systems.

# Passive Radio Sounding

Autocorrelate  
Direct Signal Only

Autocorrelate  
Direct Signal with Echo

+

*Echo signal delayed and attenuated*

Noise only correlates with self at delay of 0

Noise correlates with self at delay of 0 AND echo delay!

- Something creates a strong noise-like signal for you (“passive”)
- Treat noisy signal like a unique code, similar to GPS (except you don’t know what it will be)
- Autocorrelation of random noise against itself will be low at non-zero delays
- If there is an echo of the noise in the signal, you will have a small peak off zero delay!
- Delay of peak is related to extra time (distance) travelled by echo ( $\Delta x \approx c * \Delta t / 2$ )

# Problem: Burst are Noise-like, NOT Noise

Correction to near spectral flatness is the goal!

# Primer: Echoes and Spectra

Echoes in the time domain create ripples in frequency domain

Signal with Echo:

$$g(t) = \delta(t) + \rho\delta(t - t_d)$$

*Echo scaled by rho, delayed*

*Example signal is delta function*

FFT of Signal with Echo:

$$G(f) = \mathcal{F}[g(t)] = \int_{-\infty}^{\infty} (\delta(t) + \rho\delta(t - t_d))e^{-i2\pi ft} dt$$

$$= e^{-i2\pi f0} + \rho e^{-i2\pi ft_d} = 1 + \rho(\cos(2\pi ft_d) - i \sin(2\pi ft_d))$$

*Echo component varies with frequency!*

# Primer: Echoes and Spectra

Ripples in frequency domain create replicas in time domain

Representation of amplitude distortion:

$$A(f) = KH(f) = H(f) + H(f)b \cos(2\pi ft_c)$$

$$\begin{aligned} \mathcal{F}^{-1}[K] &= \int_{-\infty}^{\infty} (1 + a)e^{i2\pi ft} df = \int_{-\infty}^{\infty} e^{i2\pi ft} df + \int_{-\infty}^{\infty} b \cos(2\pi ft_c)e^{i2\pi ft} df \\ &= \delta(t) + \underbrace{\frac{b}{2}(\delta(t + t_c) + \delta(t - t_c))}_{\text{Replica pair!}} \end{aligned}$$

*Replica pair!*

Representation of phase distortion:  $\tilde{\phi}(f) = \phi(f) + p \sin(2\pi ft_c)$

$$\begin{aligned} A(f) &= |H(f)|e^{i\tilde{\phi}(f)} = |H(f)|e^{i\phi(f) + ip \sin(2\pi ft_c)} \\ &= H(f)e^{ip \sin(2\pi ft_c)} \quad \leftarrow p \text{ assumed small} \\ &\approx H(f)(1 + ip \sin(2\pi ft_c)) \end{aligned}$$

$$\begin{aligned} \mathcal{F}^{-1}[1 + ip \sin(2\pi ft_c)] &= \int_{-\infty}^{\infty} e^{i2\pi ft} df + \int_{-\infty}^{\infty} ip \sin(2\pi ft_c)e^{i2\pi ft} df \\ &= \delta(t) + \underbrace{\frac{p}{2}(\delta(t + t_c) - \delta(t - t_c))}_{\text{Replica pair!}} \end{aligned}$$

*Replica pair!*

# Overview

1. Study and Characterize Jovian Bursts with LWA1 Data
2. Simulate “burst-like” signals using actual burst spectra
3. Develop corrective techniques to “flatten” the spectra
4. Apply techniques to simulated bursts, observe results

# Jovian Bursts

Long Wavelength Array (LWA) observes Jovian bursts!

Spectrogram (and profiles) show activity in the 15-35 MHz range

# Identifying Useful Bursts

Detection and selection of useful bands in spectra

1s averaged profiles

Spectrum during burst activity

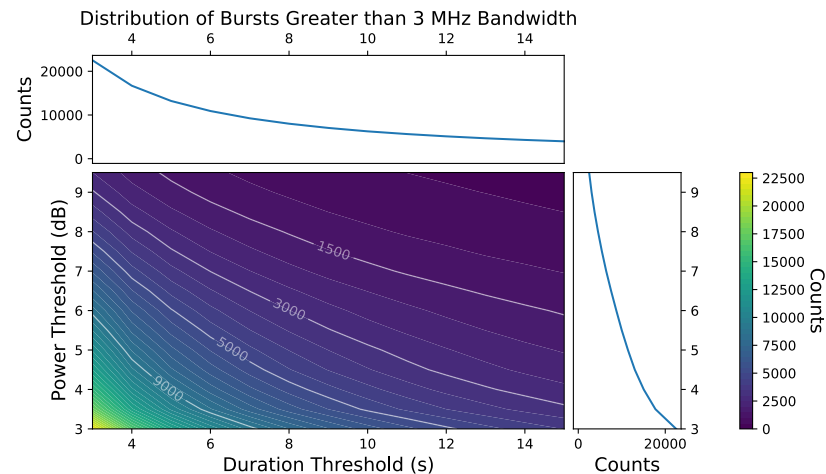

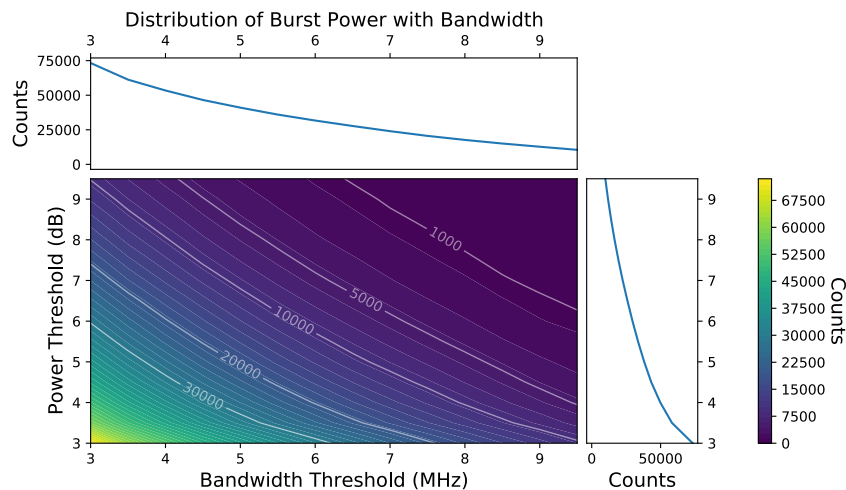

Bursting spectrum (blue) normalized by baseline (black) to yield the "Power Modulation" function

## Jovian Bursts Statistics

- 400 hours of LWA data yielded 18 hours of burst signals usable for sounding
- Criteria for “useful” is a continuous bandwidth of 3 MHz at least 3 dB above baseline
- Plots show distributions of power with bandwidth and sustained duration

Duration metric useful for series of localized measurements

## Excluding Powerful Spectra and RFI

- Analysis of these bursts revealed potential RFI
- Only bursts with peaks modulation 7-25 dB above back used
- Left with 65000 1-sec usable burst durations

# Simulating Jovian Signals

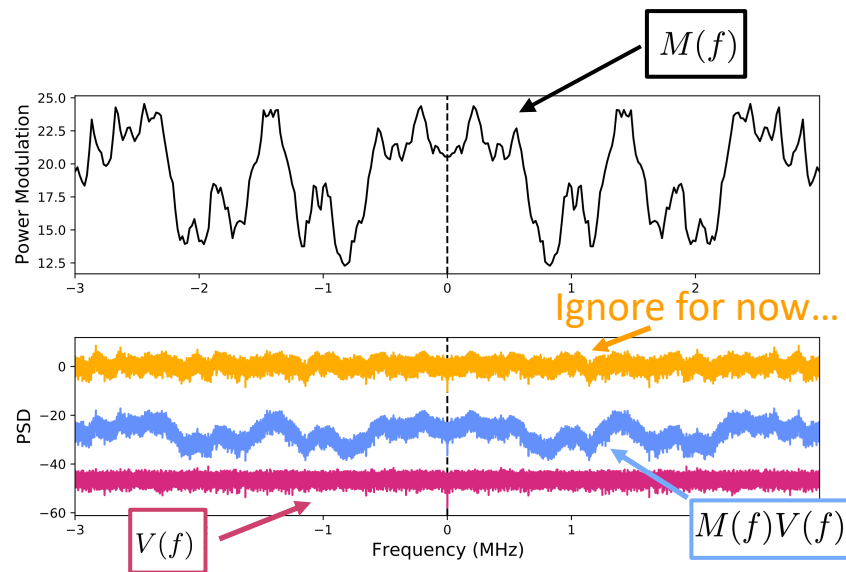

## Simulation Process:

1. Extract profile from “useful” bands
2. Create “baseline” spectrum  $M(f)$
3. Create baseline noise signal  $v(t)$
4. Take FFT of signal  $V(f) = \mathcal{F}[v(t)] = \int_{-\infty}^{\infty} v(t)e^{-i2\pi ft} dt$
5. Modulate the spectral amplitude  $M(f)V(f)$
6. Take IFFT for the simulated signal

**Direct Signal:**  $\mathcal{F}^{-1}[M(f)V(f)] = v_J(t)$

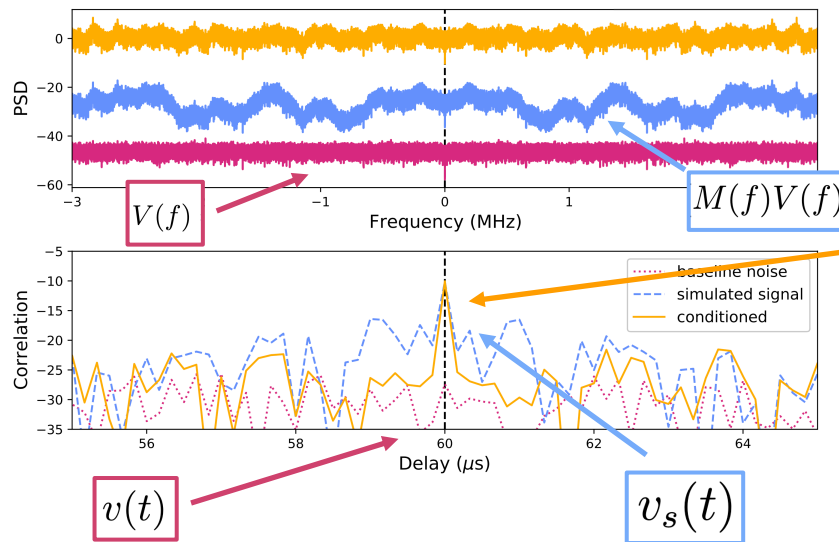

7. Create scaled, delayed “echo”

**Total Signal:**  $v_s(t) = v_J(t) + \rho v_J(t - t_d)$

# Autocorrelation (the Measurement)

But this narrow peak would be a lot better!

Autocorrelation of original noisy signal shows no peak at echo delay

Autocorrelation of “simulated burst” signal shows broad peak w/ lobes at 60 us

# Conditioning Process

# Conditioning Process

$$V_{tot,n}(f) = \int_{-\infty}^{\infty} v_{tot,n}(t) e^{-i2\pi ft} dt \quad v_{tot,n}(t) = v_{J,n}(t) + \rho v_{J,n}(t + t_d) + v_{G,n}(t)$$

$$= |V_{J,n}(f)| e^{-i2\pi ft_0} + \rho |V_{J,n}(f)| e^{-i2\pi f(t_0 + t_d)} + |V_{G,n}(f)| e^{i\phi_n(f)}$$

$$S_{tot,n} = V_{tot,n}(f) V_{tot,n}^*(f)$$

$$= |V_{J,n}|^2 (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \gamma_n + |V_{G,n}|^2$$

Noise term from Galactic Background Noise (GBN)

$$S_{SRR,n} = \int_{-\infty}^{\infty} \left[ \langle |V_G|^2 \rangle + \alpha^2 M_n^2(f') (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \gamma_n + |V_{G,n}|^2 \right] B(f - f') df'$$

Using...

$$|V_{J,n}| = \alpha M_n(f) \sqrt{\langle |V_G|^2 \rangle}$$

# Conditioning Process: Low Noise Case

Assuming low noise (large alpha):

$$S_{SRR,n} \approx \langle |V_G|^2 \rangle \alpha^2 M'^2(f), \quad M'^2(f) \equiv \int_{-\infty}^{\infty} M^2(f') B(f - f') df'$$

$$\hat{S}_{tot,n}(f) = \frac{S_{tot,n}(f)}{S_{SRR,n}(f)} \quad \begin{matrix} \text{(Blue)} \\ \text{(Red)} \end{matrix}$$

For case when we can ignore background noise:

$$\hat{S}_{tot,n}(f) = \frac{S_{tot,n}(f)}{S_{SRR,n}} \approx \frac{\langle |V_G|^2 \rangle \alpha^2 M_n^2(f) (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \gamma_n + |V_{G,n}|^2}{\langle |V_G|^2 \rangle \alpha^2 M'^2(f)}$$

Conditioning Ratio

$$\approx \frac{M_n^2(f)}{M'^2(f)} (1 + 2\rho \cos(2\pi f t_d) + \rho^2)$$

Echo Component

# Effects of Conditioning

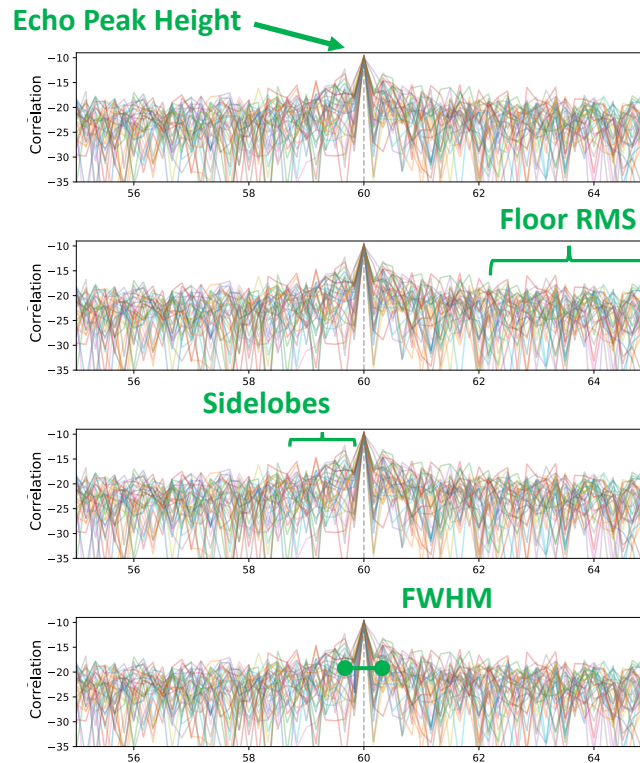

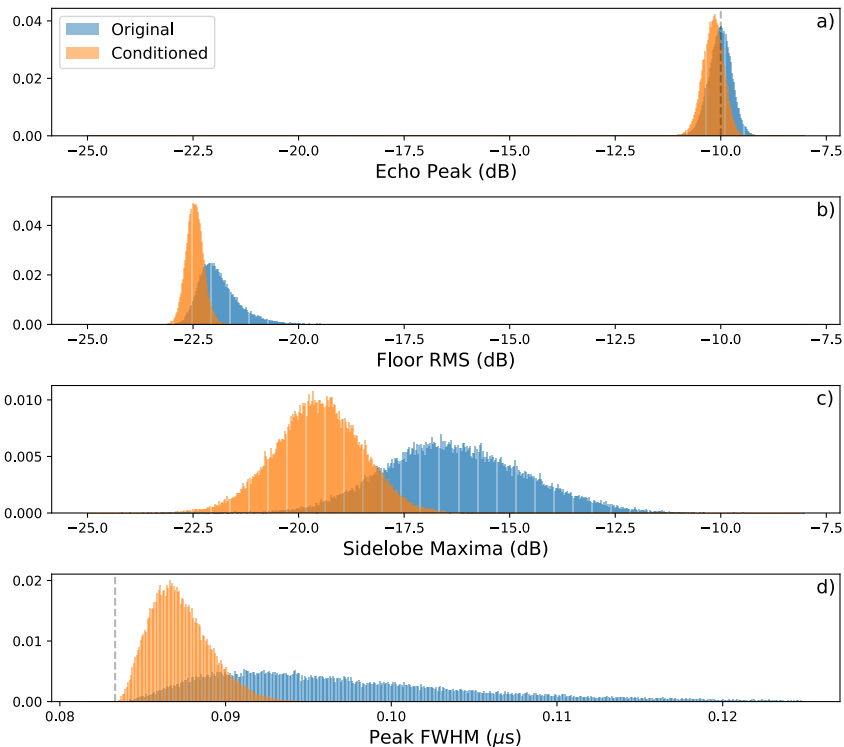

To observe the effects of condition we:

1. Use LWA to simulate 65000 burst signals
2. Autocorrelate, look at the echo delay
3. Apply conditioning process to all signals
4. Autocorrelate, look at the echo delay
5. Compare!

# Effects of Conditioning

# Adding Noise to the Signal

*So far only considered terms  
from direct signal and echo*

$$S_{tot,n} = |V_{J,n}|^2(1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \underbrace{\gamma_n + |V_{G,n}|^2}_{\text{noise terms}}$$

*But what about  
these noise terms?*

*Looking at cases where the Galactic Background Noise (GBN) is increasingly large,*

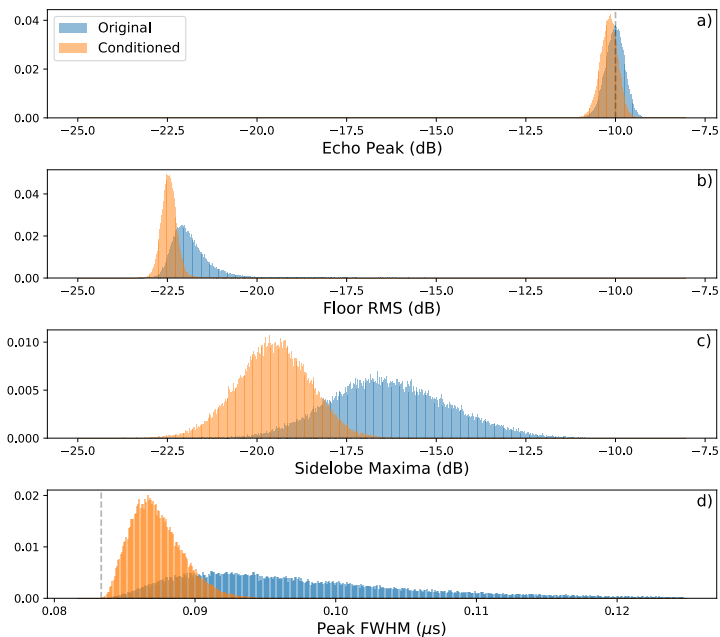

$$\text{SNR}_p = \frac{\langle |V_J|^2 \rangle}{\langle |V_G|^2 \rangle} \propto \alpha^2$$

*Not only is the correlation reduced, but so  
are the improvements from conditioning*

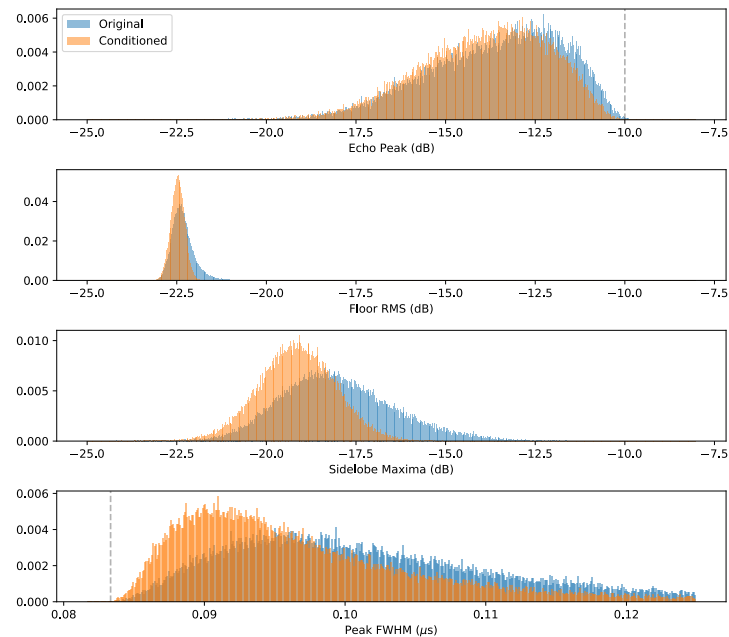

# Adding Noise to the Signal

Earlier case with no added noise

Reduced improvement for noisy signals

# Treating Noisy Signals: Ensemble Averaging

$$\begin{aligned}
 \langle S_{tot} \rangle &= \frac{1}{N} \sum_{n=1}^N S_{tot,n} \\
 &= \frac{1}{N} \sum_{n=1}^N |V_{J,n}|^2 (1 + 2\rho \cos(2\pi f t_D) + \rho^2) + \gamma_n + |V_{G,n}|^2 \\
 &= \frac{1}{N} \sum_{n=1}^N \alpha^2 M_n^2(f) \langle |V_G|^2 \rangle (1 + 2\rho \cos(2\pi f t_D) + \rho^2) \\
 &\quad + \frac{1}{N} \sum_{n=1}^N |V_{G,n}|^2 + \frac{1}{N} \sum_{n=1}^N \gamma_n \\
 &\approx \alpha^2 \langle M^2(f) \rangle \langle |V_G|^2 \rangle (1 + 2\rho \cos(2\pi f t_D) + \rho^2) + \underbrace{\langle |V_G|^2 \rangle}_{\text{noise floor}}
 \end{aligned}$$

**Ensemble (incoherent) averaging yields a noise floor to PSD**

$$\begin{aligned}
 \langle S_{SRR,n} \rangle &= \langle |V_G|^2 \rangle \alpha^2 M'^2(f) + \frac{1}{N} \sum_{n=1}^N \gamma_n + \frac{1}{N} \sum_{n=1}^N |V'_{G,n}|^2 \\
 &\approx \langle |V_G|^2 \rangle \alpha^2 M'^2(f) + \langle |V_G|^2 \rangle \quad (\text{For sufficiently large } N)
 \end{aligned}$$

**Measure modulation from ensemble spectrum, which includes an offset**

# Treating Noisy Signals: Redefine Conditioning

Divide by ensemble

$$\hat{S}_{tot,n}(f) = \frac{S_{tot,n} - \langle |V_G|^2 \rangle}{\langle S_{SRR} \rangle - \langle |V_G|^2 \rangle}$$

$$= \frac{\langle |V_G|^2 \rangle \alpha^2 M_n^2(f) (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \gamma_n + |V_{G,n}|^2 - \langle |V_G|^2 \rangle}{\langle |V_G|^2 \rangle \alpha^2 M'^2(f)}$$

$$= \frac{M_n^2(f)}{M'^2(f)} (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \frac{\gamma_n}{\langle |V_G|^2 \rangle \alpha^2 M'^2(f)} + \frac{\langle |V_G|^2 \rangle (\psi_{G,n} - 1)}{\langle |V_G|^2 \rangle \alpha^2 M'^2(f)}$$

Subtract the offsets

Conditioning Ratio

$$= \frac{M_n^2(f)}{M'^2(f)} (1 + 2\rho \cos(2\pi f t_d) + \rho^2) + \underbrace{\frac{\gamma_n}{\langle |V_G|^2 \rangle \alpha^2 M'^2(f)} + \frac{\psi_{G,n} - 1}{\alpha^2 M'^2(f)}}_{\text{Vary realization to realization}}$$

Vary realization to realization

Average many spectra/correlations to achieve conditioning:

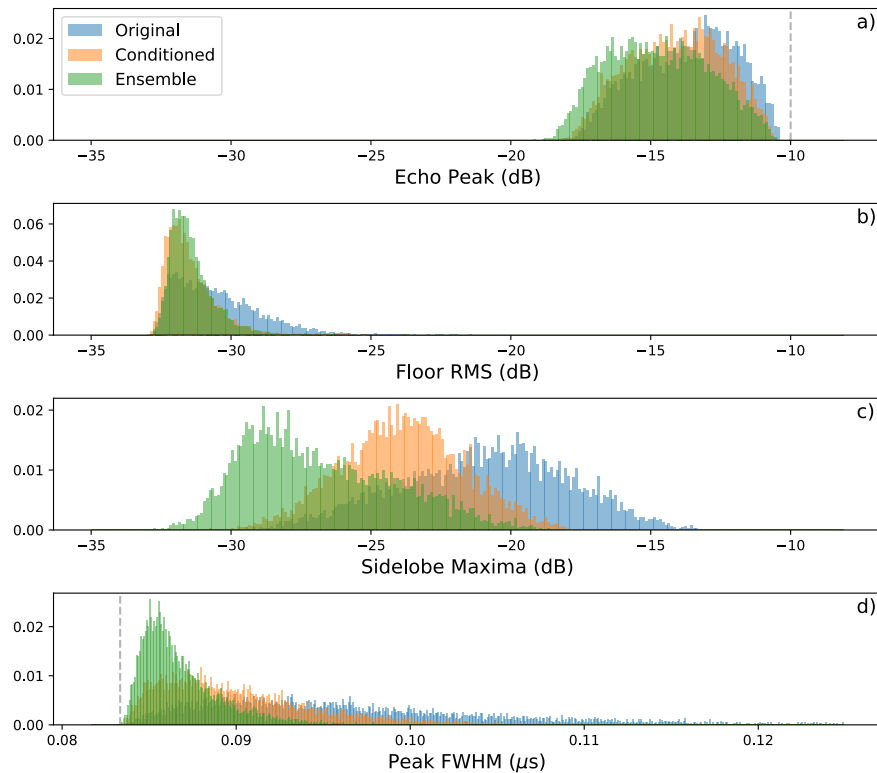

$$\langle \hat{S}_{tot,n}(f) \rangle \approx \frac{\langle M^2(f) \rangle}{M'^2(f)} (1 + 2\rho \cos(2\pi f t_d) + \rho^2)$$

$$\hat{C}_{v_J, \rho v_J}(t) = \int_{-\infty}^{\infty} \frac{\langle M^2(f) \rangle}{M'^2(f)} 2\rho \cos(2\pi f t_d) e^{i2\pi f t} df$$

Correlation at echo

# Improved Conditioning for Noisy Signals

## Conclusions and Next Steps

**These results are important in that:**

- **Applicability of Jovian bursts for sounding has been characterized statistically**
- **Problematic features of these bursts were demonstrated**
- **Techniques were developed for Jovian-system and Earth/Moon-system noise levels**
- **These analyses should be considered for missions passively sounding with Jovian bursts**

**Continuation of this work would include:**

- **A study of the presence of phase stability (nonrandomness) in the bursts**
- **Develop conditioning for amplitude and phase issues**
- **Understanding applicability of differing burst types (location, Io/non-Io driven)**
